FETAL HEART MONITORING

DEFINITION

The aim of fetal heart monitoring is to prevent adverse perinatal outcomes by identifying fetuses with metabolic acidosis/cerebral hypoxia at a point when the process is reversible by appropriate intervention.

Fetal heart rate monitoring can be performed by regular auscultation with a fetoscope, Pinard or hand-held Doppler (Intermittent Auscultation (IA)) or by continuous electronic fetal monitoring (EFM) by cardiotocograph (CTG).

Fetal heart monitoring is discussed with women antenatally, including the recommendation for intermittent auscultation and indications for recommending EFM. Where EFM is recommended in labour, the rationale is discussed with women and informed consent gained. Women who decline continuous EFM are supported with close intermittent auscultation. Women’s wellbeing is considered and their wishes are respected in relation to monitoring. Disturbances to the woman are also minimised, eg. monitoring volume low, upright positions/mobility, and use of water for pain relief, use of CTG monitors that measure the maternal pulse via the toco instead of pulse oximeter probe.

ANTENATAL ELECTRONIC FETAL MONITORING

There is no evidence to support the routine antenatal use of EFM for fetal assessment in women with an uncomplicated pregnancy.\(^1\)

For women at increased risk of pregnancy complications current evidence has not identified differences in outcomes with the use of EFM during pregnancy, but more studies are needed.\(^1\)

There is no evidence to support EFM prior to 28 weeks gestation. Any decision to perform this level of monitoring at earlier gestation should be discussed with the Obstetric consultant and justification documented.

Any decision to perform EFM to assess fetal wellbeing between 28-37 weeks of gestation will be based on clinical indication and should be discussed with the Obstetric team.

EFM is not appropriate in any case of suspected intrauterine fetal demise, ultrasound scan is recommended as the initial investigation.

Interpretation of antenatal EFM is the same as intrapartum with the added considerations of:

- An isolated small variable deceleration is not usually significant on an antenatal CTG if the remainder of the CTG is normal. However, all decelerations on an antenatal CTG require obstetric or senior midwifery review.
- Most decreased baseline variability is due to normal fetal sleep. If decreased variability continues for more than 40 minutes, in spite of manoeuvres to encourage fetal movements, obstetric review is required.
• During electronic fetal monitoring it is recommended the hand held patient event marker is used by the woman to clearly determine fetal movements. The automatic fetal movement detector (FMD or Actogram) is not a reliable method for detecting fetal movement as it can be triggered by low velocity movement.

USE OF ANTENATAL CTG IN A PRIMARY UNIT (REFER APPENDIX 3)
Primary units offering antenatal CTG for rural women, provide this service for the following:

• Reduced fetal movements on first presentation only.
• As indicated by the obstetric team following consultation with Christchurch Women’s Maternity Outpatient Department. Any concerns please fax to Day Assessment Unit (DAU) at 03 364 4471.

If any concerns on antenatal (not in labour) fetal heart auscultation consult with CWH obstetric team and consider CTG.

USE OF INTRAPARTUM EFM IN A PRIMARY UNIT
This is not recommended or supported.

INTRAPARTUM CARE

Initial assessment to include: 3
• Risk factors for increased fetal compromise (refer to Appendix 1)
• Abdominal palpation to assess lie, presentation, position, descent, growth and liquor volume, including plotting fundal height on a customised G.R.O.W. chart
• Usual pattern of fetal movements
• Assessment of uterine activity – frequency, length, strength, resting tone, uterine irritability and tenderness
• Maternal pulse – recorded to distinguish from fetal heart

The decision for mode of fetal monitoring is made in discussion with the woman, taking into consideration her pregnancy, gestation and the presence of any risk factors.

For women in spontaneous labour with uncomplicated pregnancies, intermittent auscultation is recommended. Admission CTGs are not recommended for these women.

Women with specific risk factors (listed in appendix I) are recommended to have continuous electronic fetal monitoring EFM).

INTERMITTENT AUSCULTATION

(Refer to algorithm in Appendix 1 for suitability for intermittent auscultation.)

Intermittent auscultation is a listening and counting method and the fetal heart rate should be documented as a single number (like documentation of maternal pulse rate) instead of a range. The terminology used around IA is different from that used for CTG’s as there is not a printed trace to interpret. 3
In addition to the initial assessment for all women, document:

- **Average fetal heart rate** – determined by listening toward the end of a contraction, in the absence of fetal movements, and counting for 30-60 seconds on several occasions.
- **Fetal heart rate increases** – determined by listening during a fetal movement
- **Fetal heart rate decreases** – these should not be audible when auscultation is performed immediately after a contraction for 60 seconds in first stage

**ONGOING MONITORING USING IA**

**IA INTERPRETATION**

**Normal findings:**
- **Fetal heart rate** between 110-160 bpm
- Fetal heart increases above the average
- No fetal heart decreases below the average
- Regular rhythm

**Abnormal findings:**
- **Tachycardia** (> 160 bpm)
- **Bradycardia** (< 110 bpm)
- Gradual or abrupt **decreases in fetal heart rate**
- Changes to rhythm (irregular)

**CONTINUOUS EFM**

There is evidence that continuous CTG in labour reduces the risk of neonatal seizures compared with intermittent auscultation but there were no clear differences in cerebral palsy, infant mortality or other standard measures of neonatal wellbeing, including for women with low-risk, high-risk and preterm pregnancy. However, continuous CTG was associated with an increase in caesarean sections and instrumental vaginal births\(^2\). Access to fetal blood sampling did not appear to influence differences in neonatal seizures or other outcomes\(^2\).

A number of antenatal and intrapartum risk factors have been shown to be associated with adverse perinatal outcomes (see algorithm Appendix 1). In the presence of any of these risk factors, continuous EFM is recommended and an individualised plan is made with the woman.

For continuous EFM to be of use, uterine activity and FHR trace must be clearly recorded with minimal loss of contact. The abdominal transducer and toco are placed according to palpation findings, and adjusted with maternal and fetal position changes and descent.
Where continuous EFM is required for the substantial part of labour, and if the EFM to date is considered normal, monitoring may be interrupted for short periods of up to 15 minutes to allow for personal care (eg. toilet or shower). Such interruptions should be infrequent and not occur following any intervention that might be expected to alter the fetal heart rate (eg. medication administration, rupture of membranes).

Intrapartum fetal surveillance and its interpretation is a complex task which requires a sound understanding of fetal physiological responses to hypoxia, good pattern recognition skills and the ability to integrate this knowledge with each clinical situation. Health professionals involved in intrapartum care have a responsibility to access regular training in intrapartum fetal surveillance (see below for training recommendations). The summary of fetal heart rate patterns provided below is to be used in addition to, rather than instead of, an understanding of fundamental physiology.

NORMAL CTG

The normal CTG is associated with a low probability of fetal compromise and has the following features:

- Baseline rate 110-160 bpm
- Baseline variability of 6-25 bpm
- Accelerations 15 bpm for 15 seconds
- No decelerations

ABNORMAL CTG

All other CTGs are by this definition abnormal and require further evaluation taking into account the full clinical picture.

The following features are unlikely to be associated with significant compromise when occurring in isolation:

- Baseline rate 100-109 bpm
- Absence of accelerations
- Early decelerations
- Variable decelerations without complicating features

The following features may be associated with significant fetal compromise and require further action including consultation (Refer to page 30 RANZCOG (2014) Intrapartum fetal surveillance Clinical Guidelines – third edition):

- Fetal tachycardia > 160 bpm
- Reduced baseline variability 3-5 bpm
- Rising baseline fetal heart rate
- Complicated variable decelerations
- Late decelerations
- Prolonged decelerations
- Rising baseline FHR
The following features are very likely to be associated with significant fetal compromise and require immediate action, which may include urgent delivery:

- Prolonged bradycardia (< 100 bpm for > 5 mins)
- Absent baseline variability
- Sinusoidal pattern
- Complicated variable deceleration with reduced or absent baseline variability
- Late decelerations with reduced or absent baseline variability

CORDLESS FETAL TRANSDUCERS

EFM can be performed using cordless transducers via radio wave telemetry giving women freedom of movement while being monitored. In the event of technical issues with the wireless signal reception, standard wired monitoring should be resumed.

The following requirements should be met prior to making the decision for cordless monitoring:

- Health professionals using this equipment must be familiar with instructions for use (DVD and booklet available from Birthing Suite Clinical Coordinators or Midwifery Educators).
- A minimum period of standard wired EFM is required to confirm fetal well-being before commencement of cordless EFM, including maternal pulse oximetry, to ensure accurate cordless monitoring.
- If a woman is mobilising during EFM, the chance of losing the signal or detecting the maternal heart rate is higher than for standard wired EFM, and requires extra vigilance from health professionals around regular checking of maternal heart rate and position of transducers. Ensure that women stay within range of the base unit, i.e. the same corridor as her room.
- Cordless transducers may be used while woman is in birthing pools.
- Use of the ‘MONICA’ cordless GTG
  - Generally most appropriate for women with an increased BMI and for whom continuous fetal monitoring is difficult due to maternal habitus. Use is decided on a case by case basis.
  - Health professionals using the MONICA need to be familiar with its use, including the skin preparation.
  - Extra vigilance required from health professionals around regular checking of maternal heart rate and position of transducers
  - MONICA must NOT be used in water or with multiple pregnancies.
  - Changing the ECG electrodes is necessary every 24 hours. Observe for skin irritation.

FETAL SCALP ELECTRODES

The use of a fetal scalp electrode (FSE) is indicated when there is significant loss of contact with an abdominal trace which cannot be rectified with palpation and repositioning of transducer.

- Contraindications to FSE: known maternal infection, eg. HIV, hepatitis B&C viruses, active herpes simplex virus or evidence of intrauterine sepsis. Group B Streptococcus carrier status does not preclude FSE
- History of genital herpes – avoid FSE if possible unless benefits outweigh risks
• Prematurity < 34 weeks unless the following apply:10
  – it is not possible to monitor the fetal heart rate using either external cardiotocography or intermittent auscultation
  – it has been discussed with a senior obstetrician
  – the benefits are likely to outweigh the potential risks
  – the alternatives (immediate birth, intermittent ultrasound and no monitoring) have been discussed with the woman and are unacceptable to her

• Face, brow or uncertain presentation

• Bleeding disorder such as suspected fetal thrombocytopenia, haemophilia or known maternal autoimmune thrombocytopenia

ABNORMAL FETAL HEART RATE

In clinical situations where the fetal heart rate is considered abnormal, whether using IA or continuous EFM, correct action includes:

• Checking maternal pulse/attach maternal probe if not recorded by toco
• Checking positioning of CTG transducer
• Maternal position change to increase utero-placental perfusion and/or alleviate cord compression
• Continuing or commencing continuous EFM
• Identification of any reversible cause of the abnormality and initiation of appropriate action (eg. correction of maternal hypotension, cessation of oxytocin infusion* and/or acute tocolysis for excessive uterine activity)
• Consideration of fetal blood sampling
• Escalation of care

*NOTE: In certain circumstances, oxytocin infusion may be reduced rather than discontinued, in order to maintain dose sufficient for continuing augmentation of labour but without hyperstimulation. If CTG is abnormal but unlikely to be associated with fetal compromise, the trace must be reviewed by the obstetric team prior to decision is made on continuing dose of oxytocin for augmentation.

FETAL BLOOD SAMPLING

The increased intervention rate associated with EFM can be reduced with the use of fetal blood sampling (FBS).3

Fetal blood lactate sampling is easier to perform as it requires a smaller sample size. In addition to testing fetal blood lactate it is recommended that pH is tested if sufficient blood sample is available. Lactate level gives a more direct measure of metabolic acidosis than pH, as it measures a metabolite of anaerobic metabolism. The following are recommended actions according to lactate level and pH level.9
LACTATE  |  pH     | CLASSIFICATION     | ACTION                                                                 |

</tbody>
</table>

As an adjunct to CTG monitoring in the active phase of labour, fetal blood sampling (FBS) for scalp pH and/or lactate should be considered in all circumstances where the CTG is abnormal.

If worsening lactates with ongoing CTG abnormality and inadequate progress, delivery to be expedited.

**INDICATIONS TO PERFORM FBS INCLUDE**
(Refer to pages 20 & 34 RANZCOG (2014) Intrapartum Fetal Surveillance Clinical Guidelines – third edition)

- Abnormal trace + clinical picture. If normal variability – no need to do FBS
- Persistent variable or late decelerations – if persistent late decelerations do not waste time doing FBS
- Unexplained reduced variability in the absence of other normal features.
- Unexplained tachycardia
- Prior to trial of assisted delivery where the CTG is abnormal (see comments below regarding fetal blood sampling at full dilatation)

Caution with FBS should be exercised with:
- Maternal Pyrexia
- Evidence of maternal sepsis
- Between 34+0 and 36+6 weeks of pregnancy discuss the possible use of FBS if the benefits\(^5\) are likely to outweigh potential risks.
- Full dilatation – second stage is naturally accumulative of lactic acids in both mother and fetus and not necessarily associated with hypoxia.

In the presence of infection fetal condition can change rapidly. Fetal blood sampling may be of less value in the presence of pyrexia, as it assesses hypoxia/acidaemia and not sepsis. Therefore the results of fetal blood sampling, if reassuring, should be interpreted with caution.

In general it is reasonable to perform fetal blood sampling in the passive phase of second stage. In the active phase of the second stage maternal lactate rises by 2mmol/l for every 30 minutes of active pushing.\(^5\) The fetal lactate rises correspondingly, and may be difficult to interpret. FBS may be appropriate before a ‘trial’ of instrumental delivery, but if delivery is assured at a low station with OA presentation, then proceeding direct to assisted delivery without FBS may be expedient.
Where more than one sample is obtained, the 1\textsuperscript{st} sample should be tested. If a result is achieved, discard all other sample(s).

**CONTRA-INDICATIONS TO FBS**

(Refer to pages 20 & 34 RANZCOG (2014) Intrapartum Fetal Surveillance Clinical Guidelines – third edition)

- Clear evidence on CTG of serious fetal compromise, eg. prolonged fetal bradycardia where urgent birth is required/chronic hypoxic late decelerations, sinusoidal trace.
- Significant fetal compromise in second stage of labour where assisted vaginal birth is appropriate
- Known maternal infection, eg. HIV, hepatitis B&C viruses, active herpes simplex virus or evidence of intrauterine sepsis. Group B Streptococcus carrier status does not preclude FBS
- Prematurity < 34 weeks
- Face, brow or uncertain presentation
- Bleeding disorder such as suspected fetal thrombocytopenia, haemophilia or known maternal autoimmune thrombocytopenia

The threshold for FBS should be reduced in the presence of other risk factors such as meconium, known IUGR or oligohydramnios. Scalp pH/lactate results should be interpreted taking into account any prior pH/lactate measurement, the rate of progress in labour and any other risk factors.

After a normal FBS result, sampling should be repeated at an interval of 40 to 60 minutes if the CTG remains abnormal or sooner if there are new abnormalities.

After a borderline FBS result, sampling should be repeated at an interval of 20 to 30 minutes if the CTG remains abnormal or sooner if there are new abnormalities.

If the CTG remains unchanged and the FBS result is unchanged at the second test, a further sample may be deferred unless additional abnormalities develop on the trace.

Where FBS sampling is considered necessary for a third separate occasion, a consultant/specialist obstetric opinion should be sought prior.

If worsening lactates with ongoing CTG abnormality and inadequate progress, delivery to be expedited.

**Following any labour where FBS has been performed, paired cord samples should be taken at birth to confirm acid-base status of the baby.**
UTERINE ACTIVITY MONITORING

If there are difficulties in obtaining a clear recording of uterine contractions on a CTG despite adjusting the toco, contractions must be recorded manually on the CTG itself. This is achieved by using the fetal movement button to record the start and the end of the contraction and then drawing a bracket between the two markers on the CTG paper.

NB.: marking the CTG paper with a pen at the time of the contraction will result in inaccurate recording. It takes 1 minute for the paper to appear out of the machine so marking the paper by hand will be 1 minute earlier than the actual event.

EXCESSIVE UTERINE ACTIVITY

IN THE ABSENCE OF FETAL HEART RATE ABNORMALITIES

In the presence of excessive uterine activity (defined as either):

- Tachysystole (more than five active labour contractions in ten minutes, without fetal heart rate abnormalities), or
- Uterine hypertonus (contractions lasting more than two minutes in duration or contractions occurring within 60 seconds of each other, without fetal heart rate abnormalities)

Appropriate management of uterine hypertonus or tachysystole should include:

- Continuous electronic fetal monitoring;
- Consider reducing or ceasing oxytocin infusion;
- Maternity staff remaining with woman until normal uterine activity is observed;
- Tocolysis may be considered.

EXCESSIVE UTERINE ACTIVITY IN THE PRESENCE OF FETAL HEART RATE ABNORMALITIES

Appropriate management of uterine hyper stimulation should include:

- Continuous electronic fetal monitoring;
- Reducing or ceasing oxytocin infusion;
- Maternity staff remaining with the woman until normal uterine activity is observed;
- Consideration of tocolysis; before
- Consideration of urgent delivery

Maternity care providers should be familiar with and have a protocol for acute tocolysis (relevant to the level of service) in the event that uterine hyperstimulation occurs.
Tocolytic regimens available may include:
- Terbutaline, 250 micrograms subcutaneously or IV (Grade C) – on birthing suite
- GTN, 100-200 micrograms IV – in theatre

**DOCUMENTATION**

Both IA and continuous EFM require careful documentation. All staff asked to review a CTG must record their findings.

When using IA, the fetal heart rate is documented as a single number, ie. 136 bpm and not as a range of numbers. The timing and duration are documented as well as the equipment used to listen to the fetal heart.3

Partograms may be useful during EFM and IA as it may provide visual clues to changes in the fetal heart rate such as a rising baseline.

**WHEN COMMENCING A CTG ALWAYS**

- Attach the woman’s identification label to the CTG paper
- Check the time and date stamp and paper speed and sign as correct on CTG paper
- Document in the clinical record the time and date of commencement of CTG
- Document the maternal pulse on the CTG paper / continuous maternal heart rate

**WHILE CTG IS IN PROGRESS**

- Record significant events on the CTG paper, eg. vaginal examinations, insertion of epidural, episodes of vomiting or hypotension, fetal blood sampling.
- Document maternal pulse on the CTG paper if there is a break in recording or if there is a sudden change in baseline rate. Use continuous maternal pulse rate monitoring where available with CTG. Many CTG machines record this automatically via the toco. The pulse oximeter is not required for these machines unless SpO₂ is explicitly required.
- Ensure that any member of staff who is asked to provide an opinion signs the trace and documents in the woman’s clinical record the plan of care along with the date, time and signature.
- A CTG sticker to be used by medical and midwifery staff when documenting in the clinical record. (Ref. 7329)
- A documented systematic assessment to be undertaken at least every hour.
- Where there is a concern about fetal wellbeing all midwifery staff to complete the CTG sticker tool to assess the CTG features prior to requesting a review by the senior midwife, preferably in the first instance, or medical staff. When a CTG is reviewed, the reviewer is to also sign the CTG sticker.
**NOTE:** *CTG sticker to be used in conjunction with this guideline and training programme as described below, (eg. indications for CTG listed in Appendix 1, action for correction of reversible causes summarised above in ‘Management of Abnormal Fetal Heart Rate’).*

**AT COMPLETION OF CTG**

- Following birth, sign the CTG paper and note the date, time and mode of birth.
- Store CTG paper securely with the woman’s clinical record at the end of the monitoring process.
- Multiple CTG’s need to be numbered in chronological order.

**EDUCATION AND TRAINING**

It is acknowledged that these guidelines need to be complemented by a comprehensive and ongoing education and training programme.

Fetal monitoring training is mandatory for all CDHB health professionals undertaking any aspect of EFM, and is a strong recommendation for all self-employed Lead Maternity Carers (LMC’s) (No charge to attend).

From 2018, the CDHB staff requirements for Fetal Surveillance Education Programme (FSEP) are as follows:

- Half day RANZCOG FSEP Refresher OR
- Online RANZCOG OFSEPlus

Extra education is available anytime with the free version of OFSEP.

The full day RANZCOG FSEP programme is for new staff or those requiring a more in-depth update.
A CDHB staff member with a score below 55% in their FSEP assessment requires an individual learning/supervision plan developed with their line manager and/or educator training supervisor within 3 months and re-assessment within 6 months.

APPENDIX 1: INTRAPARTUM FETAL HEART MONITORING

Intrapartum Fetal Heart Monitoring
Clinical Guidelines - Algorithm

ASK THE QUESTION!
Are there any identifiable antenatal risk factors?

NO

INTERMITTENT AUSCULTATION USING A HAND HELD DOPPLER

EFM for 30 minutes

Abnormal

Normal

ASK THE QUESTION!
Has an intrapartum risk factor developed?

NO

YES

Abnormal

Continuous EFM

Antenatal risk factors
- Increased risk of fetal compromise, including:
  - Abnormal antenatal CTG
  - Abnormal Doppler umbilical artery velocimetry
  - Suspected or confirmed intrauterine growth restriction
  - Oligohydramnios or polyhydramnios
  - Prolonged pregnancy > 42 weeks
  - Multiple pregnancy
  - Breach presentation
  - Antepartum haemorrhage
  - Known fetal abnormality which requires monitoring
  - Prior uterine scar/caesarean section
  - Pre-eclampsia
  - Diabetes (on insulin or poorly controlled or with fetal macrosomia)
  - Other current or previous obstetric or medical conditions which constitute a significant risk of fetal compromise

Intrapartum risk factors
- Induction of labour with prostaglandin/ oxytocin
- Abnormal auscultation or CTG
- Oxytocin augmentation
- Epidural anaesthesia
- Abnormal vaginal bleeding in labour
- Maternal pyrexia 38°C
- Meconium or blood stained liquor
- Absent liquor following amniotomy
- For multiparous women: active second stage of labour > 2 hours when birth is not imminent
- For multiparous women: active second stage of labour > 1 hour where birth is not imminent
- Pre-term labour less than 37 completed weeks
### Fetal Heart Monitoring Quick Reference Guide (RANZCOG 2014)

**CTG Interpretation – always take into account the FULL clinical picture (e.g. liquor colour, palpation, contractions, length of labour, infection etc.)**

**Description of CTG fetal heart rate patterns** – use this to guide completion of CTG sticker in clinical notes

<table>

</table>

**Steps for escalation** – if concerns about serious sustained fetal compromise are not heard ...

Tell the CCO – fresh eyes, clarify your concerns -> Re-emphasise concerns to the obstetric registrar

If concerns are not acknowledged, any member of team can elevate concern to obstetric SMO
APPENDIX 3: FETAL MONITORING – USING A CTG MACHINE IN A PRIMARY BIRTHING UNIT

The CTG machine is NOT to be used for laboring women in a primary birthing unit. It is only to be used for the two antenatal situations as described below.

- Maternal pulse must be monitored either continuously by way of a pulse oximeter or manually and documented regularly on the CTG printout. Many CTG machines record this automatically via the toco. The pulse oximeter is not required for these machines unless SpO₂ is explicitly required.

OCCASIONS FOR USE OF A CTG IN A PRIMARY BIRTHING UNIT

Decreased Fetal Movements (DFM)
When a woman reports DFM on the first occasion only, commence a CTG and if there are concerns at any stage of the CTG call the CWH Birthing Suite Co-ordinator (CCO) on 027 836 4673 to discuss your findings. The CCO will then liaise with the on call Registered Medical Officer. The CTG is to be faxed to Birthing Suite as required on 03 364 4717.

Follow up CTGS for rural women
Following an assessment and consultation with Christchurch Women’s Maternity Outpatient Department CTGs may be performed as part of the ongoing plan to ensure women do not have to travel in to CWH. If any concerns during daytime hours please fax to Day Assessment Unit (DAU) at 03 364 4471.

If any concerns on antenatal (not in labour) fetal heart auscultation consult with CWH obstetric team and consider CTG.

All instances of CTG use in a primary birthing unit and resultant care plans are to be fully documented.
