### Purpose

To ensure the correct administration of Dobutamine by authorised personnel.

### Scope

- CDHB IV Certificated staff competent in ECG analysis
- Medical Practitioners

### Associated documents

- [Cardiology IV Medication & IV Infusion Protocols](#), 2014
- [Notes on Injectable Drugs](#) 6<sup>th</sup> edition 2010
- [The Blue Book 12<sup>th</sup> edition](#)

### Use

Positive inotrope: low cardiac output failure. Usual dose range 2.5 microg/kg/min to 10 microg/kg/min. Rate and duration of

**The latest version of this document is available on the CDHB intranet/website only.**

administration is titrated according to heart rate, presence of ectopic activity, blood pressure and urine flow.

## Important information

- Must be administered under continuous ECG monitoring via an electronic infusion pump or syringe.
- Must be supervised by personnel trained to interpret an ECG correctly and act upon it.
- Medical staff must document any exception to this in the patient's clinical notes.
- Use a 20g cannula for administration of this medication.
- Infuse according to weight-based dose scale.
- Continuous infusion is the only method of administration. The infusion is stable for 24 hours and should be discarded if not used within this time.
- The infusion must not be interrupted for any reason e.g. showering.
- When fluid volume is of concern, e.g. Congestive heart failure, the prescriber can consider administering the appropriate dose via a syringe driver. Alternatively a double-strength infusion protocol can be utilised (Refer to Cardiology IV Medication & IV Infusion Protocols, 2014).

## Medical officer's responsibilities include

- Ensuring informed consent has been obtained from the patient.
- When prescribing Dobutamine the prescription will include:
  - Maximum increase in systolic BP
  - Maximum increase in heart rate
  - Maximum dose
  - Rate and timing (micrograms per kilogram per min) of dosage titration is area specific please refer to either local policy or Notes on Injectable drugs.

## Procedural considerations

- Refer to the Roles Responsibilities and IV policy for checking, patient identification, administration and documentation requirements.
- Check the prescribed mL per hour equates to the microg/kg/min prescribed.

**The latest version of this document is available on the CDHB intranet/website only.**

**Printed copies may not reflect the most recent updates.**

- Ensure the patient has:
  - Their current weight documented to allow for appropriate calculations using the dosage chart (refer to Notes on Injectable drugs).
  - Continuous cardiac monitoring and hourly IV site assessments and phlebitis scores are performed.
  - Diabetic patients require Q4H blood glucose monitoring for the course of the infusion.
- A full set of baseline observations are required to be documented.
- Observations are monitored at:
  - After 10 minutes,
  - After one hour
  - and then at least Q4H
  - or as the EWS management pathway indicates

## Side effects

- Hypotension, especially if the patient is hypovolaemic. This requires correcting prior to commencement of the infusion. Hypertension with an increase in systolic pressure (10-20 mmHg) and increase in heart rate 5-15 bpm. These effects are generally reversed by a reduction in dosage (elimination half-life = 2 minutes).
- Ventricular ectopic activity may be precipitated or exacerbated in a dose-related fashion in about 5% of patients.
- Dobutamine enhances atrioventricular conduction. Therefore patients with atrial fibrillation are at risk of developing a rapid ventricular response and may require digitalization prior to therapy.
- Nausea, vomiting, dysgeusia (altered taste sensations), chest pain, shortness of breath, urinary urgency and dermal necrosis.
- Possible headache and fatigue.
- Side effects would usually necessitate slowing or discontinuing the infusion according to medical orders.

## Considerations

- Dobutamine is sometimes used in combination with dopamine.
- Infusions have been continued for up to 3-5 days although tolerance has been reported with use >72 hours.

**The latest version of this document is available on the CDHB intranet/website only.**

**Printed copies may not reflect the most recent updates.**

- Combined with beta-blockers, dobutamine will predominantly cause alpha effects, i.e. vasoconstriction, hypertension.

## Weaning

- Weaning should be gradual, as a sudden dramatic drop in blood pressure is relatively common when the infusion is discontinued abruptly.
- A reduction of 2.5 microg/kg/min at hourly intervals, checking blood pressure with each down-titration, would usually be considered appropriate, however, wean as per medical instructions.

## Measurement/Evaluation

Incident management system

Canterbury and West Coast IV Link Clinical Practice Observation programme
